Abstract: Agrotis segetum (Denis & Schiffermüller) is an important polyphagous pest of sugar beet fields in many regions of world including Iran. Biorational pesticides are good and safe alternatives to the chemical insecticides which are compatible with goals of IPM programs. In this study, efficacy of three biorational pesticides, Azadirachtin (NeemAzal®), Bt (Bactospeine®) and Bt (Biolep®), and a conventional chemical insecticide, deltamethrin (Decis® EC), was studied on pest population and damages as well as carabid beetle population as its important predators in sugar beet field during two agricultural seasons (2015 and 2016). Sampling of the pest egg batches, larvae and the carabid beetles was carried out at 1 day before treatment (DBT) and 1, 3, 7 and 10 days after treatment (DAT). Finally, total yield and sugar content of sugar beet in the different treatments were evaluated for the two agricultural seasons. Results showed that NeemAzal was a significant oviposition deterrent for female moths of A. segetum. During both agricultural seasons, the highest and lowest larvicidal effects were observed in Decis and Bt (EC) treatments, respectively. Ten DAT, 40, 60, 13 and 73% reductions of pest population larvae were observed were observed in NeemAzal, Bt (WP), Bt (EC) and Decis treatments, respectively. Sugar beet yield in all treatments was significantly higher than control. Total yields in NeemAzal, Bt (WP), Bt (EC) and Decis treatments were 17.5, 25.6, 12.9 and 43.7% more than control in 2015 and 8.7, 19.7, 4.8 and 37.1% respectively in 2016. But sugar content in the different treatments was not significantly different. Totally, the most adverse effects on carabid beetles were recorded in Decis® treatment.

Keywords: Chemical control, biological control, Deltamethrin, cut worm

Introduction

The common cutworm (turnip moth), Agrotis segetum Denis & Schiffermüller (Lep., Noctuidae) is a polyphagous pest with a current host distribution covering 25 Families of plants. The pest was reported throughout Europe, parts of Africa and Asia (Jakubowska et al. 2005) including in all geographical regions of Iran (Feizpoor et al., 2014). After emergence, the larva feeds on the epidermis of the leaves, bites stems of seedling and cuts them, sometimes eats up the entire seedling through the stem at ground...
level and their habit changes according to their growth. It attacks the young seedling at night as a nocturnal cutworm and during the day hides and lives inside the cracks, holes and litter or in the soil sometimes to a depth of up to 10 cm. The cutworm usually causes 20-37% reduction in yield (Atwal, 1976). Due to subterranean habits of the pest, its chemical control is very difficult (Bowden et al., 1983). Nevertheless, cutworms are presently managed through application of chemical insecticides with different modes of action. But, applications of these chemicals has serious drawbacks, including reduced profits from high insecticide costs, side effects on natural enemies, development of resistance in populations and environmental pollution (Viji and Bhagat, 2001). Therefore, these adverse effects evoked the scientists to explore new ways of insect control with comparatively less persistent, safer but effective insecticides (Pedigo, 2002). Azadirachtin and Bt, are applied as two insecticides to control noctuid pests (Singh et al., 2007). Bacillus thuringiensis Berliner subspecies Kurstaki has been applied to control lepidopteran pests for approximately 60 years (Schmidt, 2009). Neem or its main active ingredient, azadirachtin, is an environment-friendly botanical insecticide which affects the insects’ reproductive organ, body development and other endocrine systems (Senthil-Nathan, 2013). The biorational pesticide is biodegradable, mildly toxic or non-toxic to other biocontrol agents has and is usually of a low toxicity to humans and mammals (Schmutterer, 1990).

Deltamethrin as the most powerful synthetic pyrethroid has very broad through control and affects the insects’ transmission of messages sent from the brain by blocking nerve impulses and causing paralysis, which leads to fast knockdown when poisoning lasts more than a few hours (Hasibur et al., 2014).

Biological control by natural enemies (NEs) is main strategy in IPM programs. One of the major criteria for selection of a suitable pesticide in IPM program is its compatibility with NEs and biocontrol agents (Pedigo, 2002). Many natural enemies are active against A. segetum in sugar beet fields, especially carabid beetles.

The objective of the present experiments was to investigate effects of three insecticides and deltamethrin, as a conventional chemical, on A. segetum and carabid beetles as its important NE under field conditions.

Materials and Methods

Experimental design

The present experiment was carried out at the farmer’s field of Ghale Salim, Chaharmahal and Bakhtiari province, Iran (32°32’35.8”N 50°45’46.4”Elatitude and 2054 m above sea level) during two agricultural seasons, 2015-2016. Sugar beet seeds, cultivar Took an, were planted at rate of 2kg/ha. All agronomic practices like growing, fertilizing, weeding and irrigation (every 7 days) of sugar beet followed according to agriculture organization advisement of Chaharmahal and Bakhtiari province. The experimental plot area was 150m², row to row spacing 0.3m, plot to plot distance 0.5m and between the blocks, 1m. The experiment was done in a randomized complete block design.

Azadirachtin (NeemAzal® T/S EC 1), Bt (WP 90), MVP Bactospeine subsp. Kurstaki; Bt (Biolwp® EC, 10⁸ cells/ml), and deltamethrin, (Decis® EC 2.5) were applied at the rates of: 2 liter/ hectare, 2kg/hectare, 2 liter/ hectare and 1 liter/hectare, as per manufacturer’s recommendation, respectively.

Ten days after peak of the moth flight (25 June 2015 and 29 June 2016), the treatments were performed. Treatments were applied using a hand operated knapsack sprayer having 20 liters capacity fitted with hollow cone nozzle. Control plots were sprayed with water only. The equipment was set to deliver 1000L/ha, following the growers’ usual practice.

Sampling

Ten plants were randomly selected per treatment/plot by traveling in an X-shaped pattern through each plot and all developmental stages of the pest from upper, middle and lower
portions of plants were weekly recorded. In each sampling date, 10 plants were sampled per plot. Two sex pheromone lures (Avan Mashreqh Zamin Company, Iran) were placed inside Delta sticky traps and the male flight activity was weekly monitored.

Sprayings started with beginning of A. segetum mass trapping. Density of the pest larvae on sample leaves were evaluated 1 day before treatment (DBT) and 1, 3, 5, 7 and 10 days after treatment (DAT). Sampled leaves were observed and egg patches as well as live larvae of A. segetum were counted. The percentages of A. segetum egg and larvae reductions were calculated according to Henderson and Tilton's equation (1955) to determine the field efficacy of the tested insecticides during various days after treatments.

\[
\text{Efficacy} \, (\%) = \left(1 - \frac{C_b \times T_a}{C_a \times T_b}\right) \times 100
\]

Where Cb and Ca are the number of insects in control plots before and after treatment and Tb and Ta are the number of insects in treated plots before and after treatment, respectively.

Harvesting was done on 17th October and 16th November in experiments of 2015 and 2016, respectively and total yield was separately weighed in each plot. Twenty kg of sugar beet were randomly selected from each treatment and sent to sugar content determination unit of sugar factory of Chaharmahal and Bakhtiari province.

Density of carabid beetles (Col., Carabidae) in each treatment was monitored by pit fall traps. One pit fall trap was randomly placed in each replication. Numbers of caught carabid beetles in each trap were recorded at 1 DBT and 1, 3, 7 and 10 DAT.

Data analysis

Randomized completed block design with four replications were used in the trials. Data obtained were submitted to analysis of variance (ANOVA) using F test and means were compared by Duncan's Standardized Range Test at 0.05 probability level. All analyses were done using SAS statistical software version 9.1 (SAS Institute, Inc., 2004).

Results

Effect of the insecticides on A. segetum and its damage

Among the insecticides, NeemAzal significantly reduced the pest egg batch in comparison with control. The number of egg batches in the other treatments had no significant difference in comparison to the control (Table 1). Therefore, it is demonstrated that NeemAzal was significant oviposition deterrent for female moths of A. segetum. NeemAzal treatment caused 85.1% reduction in egg patch number in 2016.

Also, there were significant differences in larval numbers in the various treatments at different DAT (Table 2 and 3). During both agricultural seasons, the highest and lowest larvicidal effects were observed in Decis and Bt (EC) treatments, respectively. In 2015, at 10 DAT, 45.4, 72.7, 45.4 and 90.9% larval reduction were observed in NeemAzal, Bt (WP), Bt (EC) and Decis treatments, respectively. In 2016, the reduction% were 35.7, 44.9, 6.9 and 47.8% in NeemAzal, Bt (WP), Bt (EC) and Decis treatments at 10 DAT, respectively. Results showed that Bt in EC formulations had no significant effect on larvae. Whereas, high insecticidal effect was recorded for WP formulation of Bt.

Results showed that in all insecticide treatments, yields of the sugar beet were significantly higher than control (Table 4). Among insecticides, the highest and lowest yields were observed in Decis and Bt (EC), respectively. Total yields in NeemAzal, Bt (WP), Bt (EC) and Decis were 17.5, 25.6, 12.9 and 43.7% more than control during agricultural season of 2015 and 8.7, 19.7, 4.8 and 37.1% during agricultural season of 2016, respectively.

The results indicated that sugar content in the different treatments was not significantly different.

Effects of the insecticides on carabid beetles

After 1 and 3 DAT, the highest and lowest detected carabid beetles were observed in NeemAzal and Decis treatments (Table 5 and 6). Totally, the most adverse effects on carabid beetles were recorded in Decis treatment. There was no significant difference between carabid beetle numbers in the other treatments. Therefore, Decis is incompatible with IPM and NE conservation programs.

Discussion

NeemAzal was significant oviposition deterrent to A. segetum moths. The findings are in line with the results of Greenberg et al. (2005) who demonstrated that neem based insecticides had significant oviposition deterrent effects on Spodoptera exigua Hubner (Lep., Noctuidae). Similar effects were reported for the azadirachtin on other noctuid moths such as S. litura Fabius (Naumann and Isman, 1995; Jayasankar et al., 2013), Sesamia calamistis Hampson (Bruce et al., 2004) and Helicoverpa armigera Hübner (Packiam et al., 2012). In contrast, it is proved that the neem based insecticides were not significant deterrent to female moths of Mamestra brassicae L. (Seljasen and Meadow, 2006).

Decis and Bt (EC) had the highest and lowest efficacies against the pest larvae. Although, NeemAzal and Bt (WP) significantly reduced the larval densities. Decis, deltamethrin, is a broad spectrum chemical insecticide which is recommended for control of A. segetum in sugar beet fields of Iran (Jalalizand, 2016). Similarly, susceptibility of Earias vitella Fabricus (Lep., Noctuidae) to deltamethrin in cotton fields was reported by Jan et al. (2015). In spite of high efficacy of the insecticide against A. segetum larvae, its residues in sugar beet crop cause serious problem in sugar factory (Jalalizand, 2016). Also, resistance to the insecticide was previously recorded for some noctuid pests such as Heliothis virescens F. (Sayyed et al., 2008) and H. armigera (Alvi et al., 2012; Hussain et al., 2014). In addition Decis had the highest adverse effect on the predator (Col., Carabidae).

Therefore, other safer insecticides such as NeemAzal and Bt (WP) are recommended as better choices for use in sugar beet fields. Molting disruption and larval mortality of Agrotis ipsilon as well as anti-feedant properties were found by feeding on azadirachtin-sprayed creeping bentgrass (George and Potter, 2008).
Also it caused feeding activity reduction at 2.5 g/L, prolonging the period of molting, and 60% moltability reduction (Senthil-Nathan, 2013). Efficacy of azadirachtin based insecticides on some noctuid pests including S. littura (Nathan and Kalaivani, 2005), S. littoralis is Biosduval (Pineda et al., 2009), Trichoplusia ni Hubner (Xian-Yan et al., 2010) and H. armigera (Abedi et al., 2014) has been previously documented.

_Bt_ is a popular option for pest control. _Bacillus thuringiensis_ is a Gram positive spore which produces proteinaceous crystals with insecticidal characteristics during sporulation that makes _Bt_ be distinct from other members of the _Bacillus cereus_ group (Rasko et al., 2005; Zenas and Crickmore, 2012). Our findings agree with the laboratory experiment results of Gao et al. (2001), who showed that _Bt_ is an effective biorational pesticide to control _A. fuscicoll_ Miwa and other underground agricultural pests (Yaping et al., 2001). Similarly, the susceptibility of some other noctuid larvae including _H. armigera_ and _H. punctigera_ Wallengren (Liao et al., 2002), _Sesamia nonagrioides_ Lefebvre and two populations of _Ostrinia nubilalis_ Hübner to endotoxins of _Bt_ were reported. These findings are in agreement with ElShafie and Abdelrahem (2012) who reported that the average yield of potato treated with NeemAzal®, a formulation of azadirachtin, was increased in comparison to control.

Our investigations showed that the least and most adverse effects on carabid beetles, as an important NE of _A. segetum_, were observed in the NeemAzal and Decis treatments.

The repellency, anti-feedant, deterrence activities (Mochiah et al. 2011), and safety to the beneficial insects make neem a sufficient pesticide for control of _A. segetum_. Several laboratory investigations have showed that azadirachtin is active against certain types of pestiferous insects but it doesn't harm several types of beneficial arthropods (Stark, 1992). This finding is in conflict with results of Scalercio et al. (2009) who stated that azadirachtin had high side effects on coleopteran predators in olive orchards. But Rondon et al. (2013) proved that the densities of carabid predators in potato field treated with azadirachtin were similar to non-sprayed field. Similarly, it is demonstrated that carabid beetles in turf grass were not affected by azadirachtin treatment (Brudea, 2009).

**Conclusion**

In spite of the higher efficacy of Decis; NeemAzal and BT in WP formulation were recommended for the pest control due to their high toxicities and protective effects against the pest and low risk to the pest’s predators including carabid beetles. Results of this study can be used in IPM program of _A. segetum_ in sugar beet fields.

چکیده: کرم طوق‌فرش Agrotis segetum (Denis & Schiffermüller) گونه‌ای قرار گرفته در بسیاری از مناطق جهان از جمله ایران می‌باشد. با کارگیری آفتابک‌های زیست‌سازگار حشرگری خوب، کم‌خطر سموم شیمیایی می‌باشد که با اهداف برخورداری از PMIP کارخانه‌های چغندرقند در این مطالعه کارایی سه حشره‌کش زیست‌سازگار آزاد‌درختی (نیم آزال، Bt) در فرولاسیون پودر و تتل، (در فرولاسیون بیشتر) به سم شیمیایی رایج (دماتریمین بیا ادامه تجارت دمو) و گروه جمعت Bt و خسارت این آفتاب و سوسک‌های کارابید (به عنوان شکارگران مهم آن) در مزرعه چغندرقند فل سال زراعی 1394-1395 مورد مطالعه قرار گرفت. نمونه‌برداری از توده‌های زراعی و لاروها آن افت DAT (DBT) به دست آمد. در روز بعد از نیم آزال افت Bt و سوسک‌های کارابید در یک روز قبل از نیم آزال بود. در طول هر دو فصل زراعی، بیشترین و کمترین اثرات حشره‌کشی حشره‌کشی محصول B. segetum (Bt) در فرولاسیون پودر و تتل دمو در ناش دار که در نیم آزال دارای خصوصیت شناسنده ماده‌ای پرداخته شد. نتایج نشان داد که هر دو دمای درصد کاهش جمعیت لارو بهترین تیمار نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جمعیت لارو بهترین تیمار در نیم آزال بود. درصد کاهش جم
